Production Plant Assessment

UTILITIES

We conducted a study of the current network infrastructure in both OT and IT environments. This includes installing passive probes (Nozomi) to assess devices within the facilities.

We performed a network-based and host-based vulnerability assessments to identify and measure the variance between the current state and the target one. Our approach involved defining an OT reference architecture based on industry standards and other best practices in the sector. This architecture ensures compliance with security recommendations identified in the assessment phase, providing a robust framework for securing your infrastructure.

The project was deployed in one of the plant as a pilot for being scaled up in the other plants of the company.
